Discriminative vs. Generative Learning

CS4780/5780 – Machine Learning Fall 2013

> Thorsten Joachims Cornell University

Reading: Mitchell, Chapter 6.9 - 6.10 Duda, Hart & Stork, Pages 20-39

Discriminative Learning

- Modeling Step:
 - Select classification rules *H* to consider (hypothesis space)
- Training Principle:
 - Given training sample $(\vec{x}_1, y_1), \dots, (\vec{x}_n, y_n)$
 - Find *h* from *H* with lowest training error
 → Empirical Risk Minimization
 - Argument: low training error leads to low prediction error, if overfitting is controlled.
- Examples: SVM, decision trees, Perceptron

Discriminative Training of Linear Rules

- Soft-Margin SVM
 - $R(w) = \frac{1}{2}w * w$
 - $\Delta(\bar{y}, y_i) = \max(0, 1 y_i \bar{y})$
- Perceptron
 - R(w) = 0
 - $\Delta(\bar{y}, y_i) = \max(0, -y_i \bar{y})$
- Linear Regression
 - R(w) = 0
 - $\Delta(\bar{y}, y_i) = (y_i \bar{y})^2$

Ridge Regression

$$- R(w) = \frac{1}{2}w * w$$

$$- \Delta(\bar{y}, y_i) = (y_i - \bar{y})^2$$

• Lasso

$$- R(w) = \frac{1}{2} \sum |w_i|$$
$$- \Delta(\bar{y}, y_i) = (y_i - \bar{y})$$

- Regularized Logistic Regression / Conditional Random Field
 - $R(w) = \frac{1}{2}w * w$
 - $\Delta(\bar{y}, y_i) = \log(1 + e^{-y_i \bar{y}})$

Bayes Decision Rule

• Assumption:

- learning task P(X,Y)=P(Y|X) P(X) is known

- Question:
 - Given instance x, how should it be classified to minimize prediction error?
- Bayes Decision Rule:

 $h_{bayes(\vec{x})} = argmax_{y \in Y}[P(Y = y | X = \vec{x})]$

Generative vs. Discriminative Models

Process:

- Generator: Generate descriptions according to distribution *P(X)*.
- Teacher: Assigns a value to each description based on P(Y|X).

Training Examples $(\vec{x}_1, y_1), \dots, (\vec{x}_n, y_n) \sim P(X, Y)$

Discriminative Model

- Select classification rules *H* to consider (hypothesis space)
- Find *h* from *H* with lowest training error
- Argument: low training error leads to low prediction error
- Examples: SVM, decision trees, Perceptron

Generative Model

- Select set of distributions to consider for modeling *P(X,Y)*.
- Find distribution that matches *P(X,Y)* on training data
- Argument: if match close enough, we can use Bayes' Decision rule
- Examples: naive Bayes, HMM

Bayes Theorem

- It is possible to "switch" conditioning according to the following rule
- Given any two random variables X and Y, it holds that

$$P(Y = y | X = x) = \frac{P(X = x | Y = y)P(Y = y)}{P(X = x)}$$

Note that

$$P(X = x) = \sum_{y \in Y} P(X = x | Y = y) P(Y = y)$$

Naïve Bayes' Classifier (Multivariate)

- Model for each class $P(X = \vec{x}|Y = +1) = \prod_{i=1}^{N} P(X_i = x_i|Y = +1)$ $P(X = \vec{x}|Y = -1) = \prod_{i=1}^{N} P(X_i = x_i|Y = -1)$
- Prior probabilities

P(Y = +1), P(Y = -1)

• Classification rule: $h_{naive}(\vec{x}) = \underset{y \in \{+1,-1\}}{\operatorname{argmax}} \left\{ P(Y = y) \prod_{i=1}^{N} P(X_i = x_i | Y = y) \right\}$

low	yes	yes	1
high	no	yes	???

Estimating the Parameters of NB

- Count frequencies in training data
 - n: number of training examples
 - n_{+} / n_{-} : number of pos/neg examples
 - #(X_i=x_i, y): number of times feature
 X_i takes value x_i for examples in class y
 - |X_i|: number of values attribute X_i can take
- Estimating P(Y)
 - Fraction of positive / negative examples in training data

$$\hat{P}(Y = +1) = \frac{n_+}{n}$$
 $\hat{P}(Y = -1)$

- Estimating P(X|Y)
 - Maximum Likelihood Estimate

$$\hat{P}(X_i = x_i | Y = y) = \frac{\#(X_i = x_i, y)}{n_y}$$

Smoothing with Laplace estimate

$$\widehat{P}(X_i = x_i | Y = y) = \frac{\#(X_i = x_i, y) + 1}{n_y + |X_i|}$$
